

# The Gamma-ray Transients Monitor (GTM) on board Formosat-8B

Hsiang-Kuang Chang

National Tsing Hua University (NTHU), Hsinchu, Taiwan

On behalf of the GTM team

## 1. Science goal:

To monitor **Gamma Ray Bursts (GRBs)**, and bright gamma-ray transients from other sources in 30 keV – 2 MeV.

## 2. Instrument design

## 3. Current status

### \* A quick summary:

FS-8B will be launched into a sun-synchronous LEO in 2026.

GTM is expected to detect about 50 GRBs per year.

GTM can detect and localize GRBs, can perform spectral analysis, and, for very bright GRBs, can measure polarization states.

A GRB detected by COSI. What is its nature?

# Gamma Ray Bursts (GRBs)

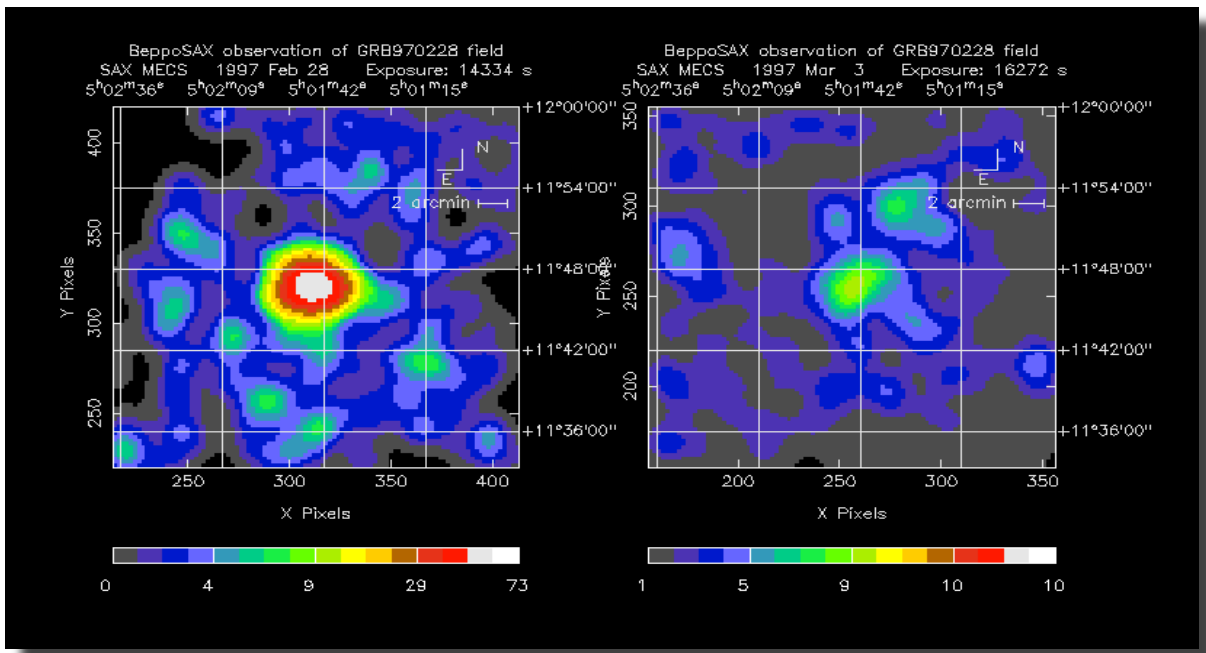

## 2704 BATSE Gamma-Ray Bursts

## Fermi GBM GRBs in first ten years of operation

GRB 970228, the first GRB afterglow observations in X-ray and optical bands.

(BeppoSAX Science Data Center (SDC) and the Agenzia Spaziale Italiana (ASI))

(P. J. Groot (U. Amsterdam) et al., WHT, INT)

(GRB 990123 – HST) (STScI)

GRB host galaxies  
and afterglows all  
show large redshifts.

(GRB 050709 – HST)

(Derek Fox/Penn State University)

# GRB models

Long GRBs:  
 hypernova, collapsar,  
 high redshift,  
 the first star

## Crashing neutron stars can make gamma-ray burst jets

Short GRBs:  
 kilonova, merger,  
 EM counterparts to  
 GW events

The birth of black holes!  
 Or?

➤ Key issues:

Observation of afterglows

Detection of host galaxies

Sky coverage

Localization capability

➤ More GRB monitors are desired to enhance sky coverage and provide better localization

Small instruments can do that.

# GTM on board Formosat-8B

The Gamma-ray Transients Monitor (GTM) consists of two identical modules located on two opposite sides of FS-8B. Each module has four sensor units facing different directions to cover the whole sky. Each sensor unit is composed of a GAGG scintillator array (51 mm x 51 mm x 8 mm) and SiPM of corresponding pixel size for readout. (Chang et al. 2022, ASR, 69, 1249)

The effective area of one GTM GAGG (Gadolinium Aluminum Gallium Garnet) sensor unit.

# FS-8B/GTM, Source and Background Models

MEGALib (Zoglauer et al. 2008)

## Background:

A polar ( $97^\circ$ ), low-altitude (560 km) Earth orbit; embedded in MEGALib.

Source spectral model:

$$N_E \propto E^\alpha e^{(-E(2 + \alpha)/E_p)}$$

Long GRBs:

$\alpha = -1$ ,  $E_p = 300\text{keV}$ , duration 10 sec

Short GRBs:

$\alpha = -0.5$ ,  $E_p = 500\text{keV}$ , duration 0.5 sec

These numbers are the median of  $t_{50}$  and corresponding spectral parameters of Konus-WIND-detected GRBs (Svinkin et al., 2016; Tsvetkova et al., 2017).

# GTM's GRB detection efficiency

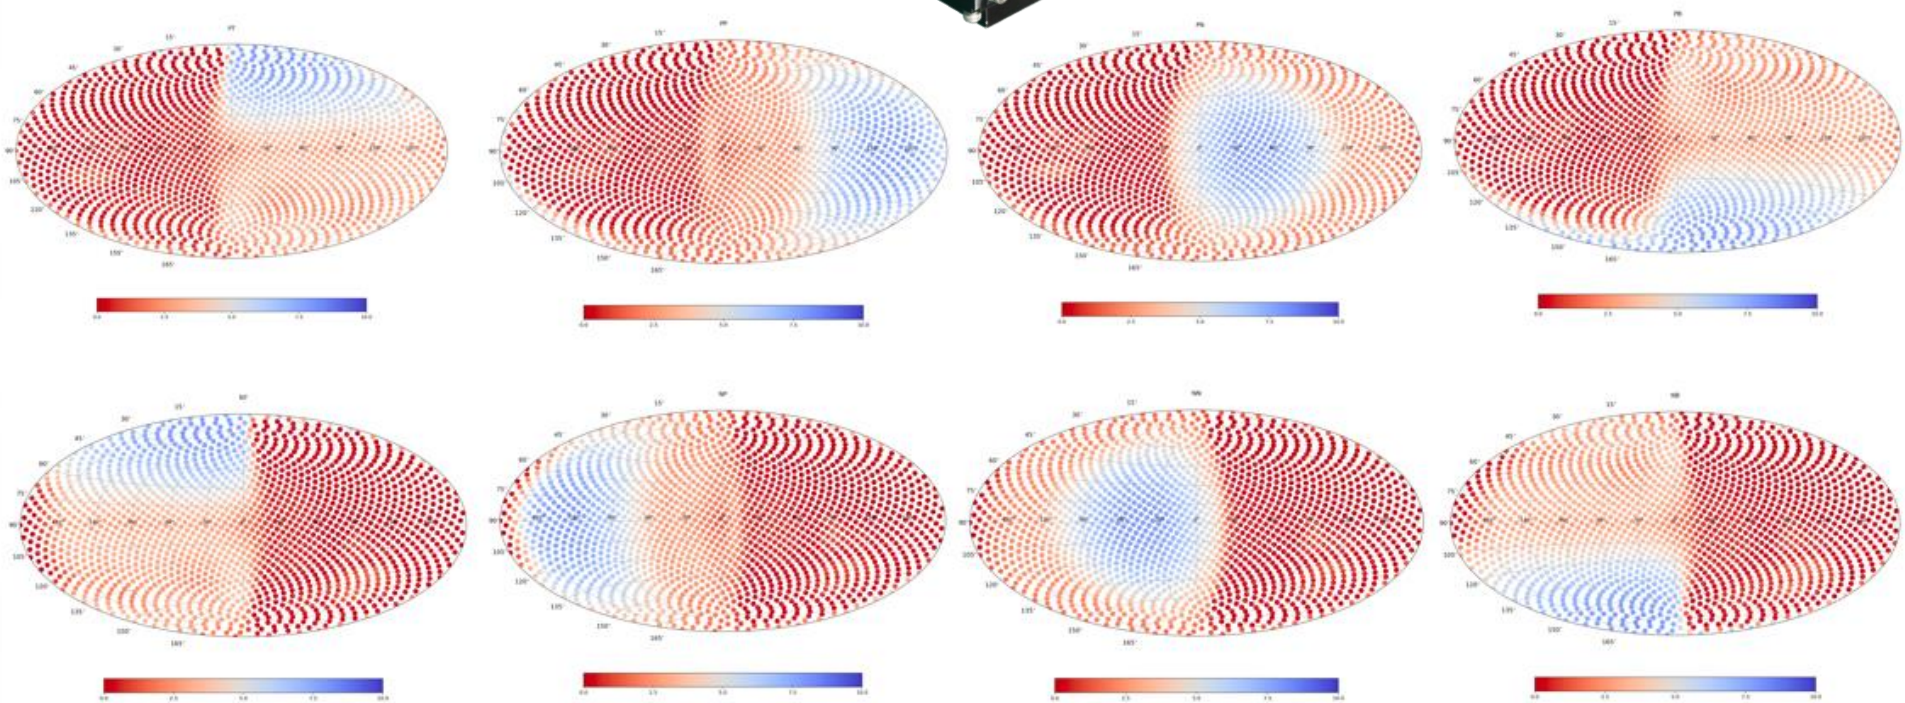

Fermi/GBM 10-year GRB fluence distribution (von Kienlin et al. 2020)

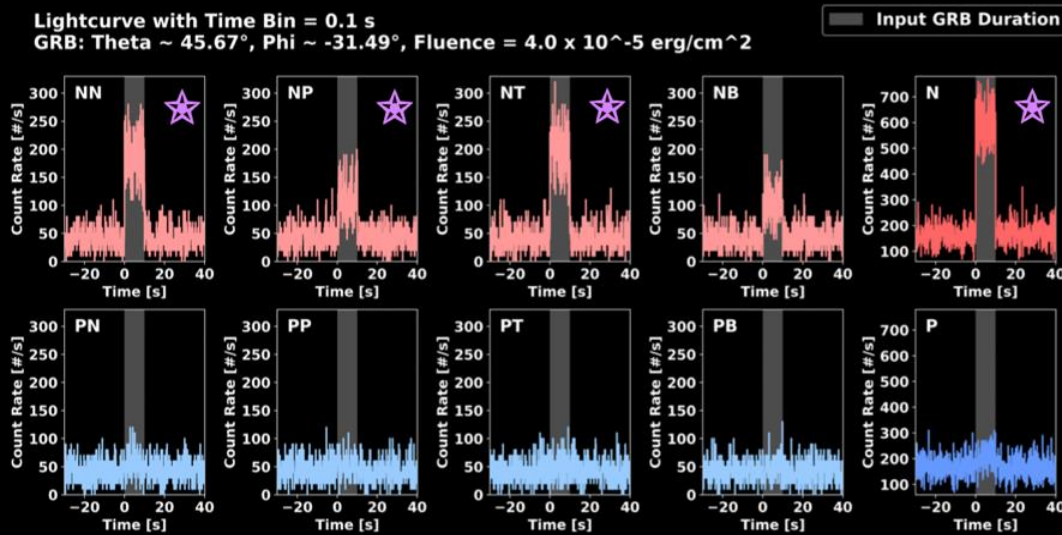

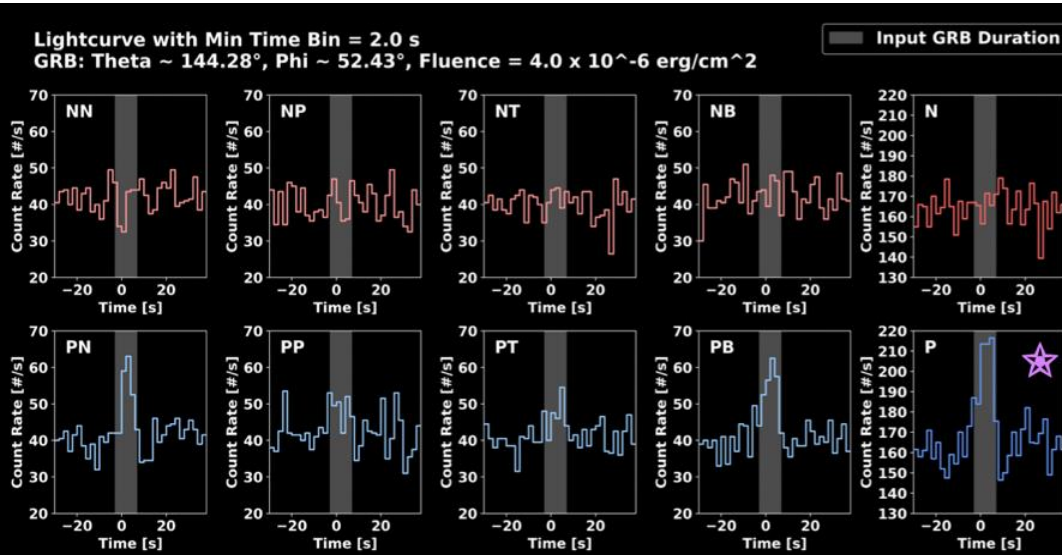

Assuming a 36% duty cycle,  
FS8B/GTM will detect about 50 GRBs per year.

# Detector response (50-300 keV) of the 8 sensors in different directions in the sky

( $\alpha = -1$ ,  $E_p = 300\text{keV}$ )

Lv. 0: raw data  
Lv. 1: decoded/calibrated data  
Lv. 2: quick data product  
Lv. 3: refined data product

## Current status (February 2025)

- FM was delivered to TASA on September 8, 2023.
- SMRR was completed on October 23, 2023.
- Calibration measurements on ground are been conducted.  
(A paper submitted to NIMA is under review.)
- Integration with FS-8B bus will be in 2025.
- Waiting for the launch in 2026.
- We are also working on a GTM successor, which is more optimized for polarization measurement.
